

TypeScript Fundamentals

21/10/2017

What is TypeScript?

"TypeScript is a typed superset of JavaScript that compiles to plain JavaScript." ~ typescriptlang.org

JavaScript Dynamic Types

- **JavaScript provides a dynamic type system**
- **The Good:**
 - Variables can hold any object
 - Types determined on the fly
 - Implicit type coercion (ex: string to number)
- **The Bad:**
 - Difficult to ensure proper types are passed without tests
 - Not all developers use ===
 - Enterprise-scale apps can have 1000s of lines of code to maintain

Flexible Options

Any Browser

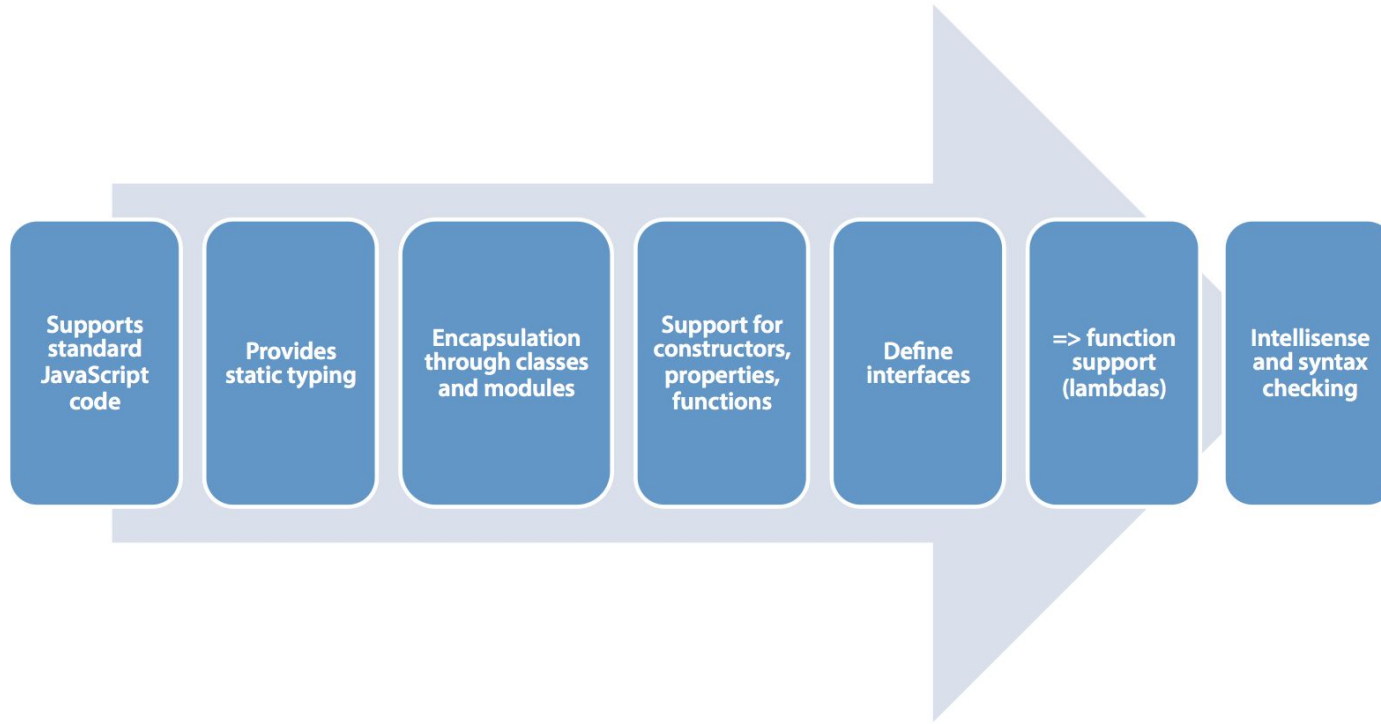

Any Host

Any OS

Open Source

Tool Support

Key TypeScript Features

TypeScript Compiler

TypeScript → JavaScript

TypeScript

Encapsulation

```
class Greeter {  
  greeting: string;  
  constructor (message: string) {  
    this.greeting = message;  
  }  
  greet() {  
    return "Hello, " + this.greeting;  
  }  
}
```

Static Typing

JavaScript

```
var Greeter = (function () {  
  function Greeter(message) {  
    this.greeting = message;  
  }  
  Greeter.prototype.greet = function () {  
    return "Hello, " + this.greeting;  
  };  
  return Greeter;  
})();
```

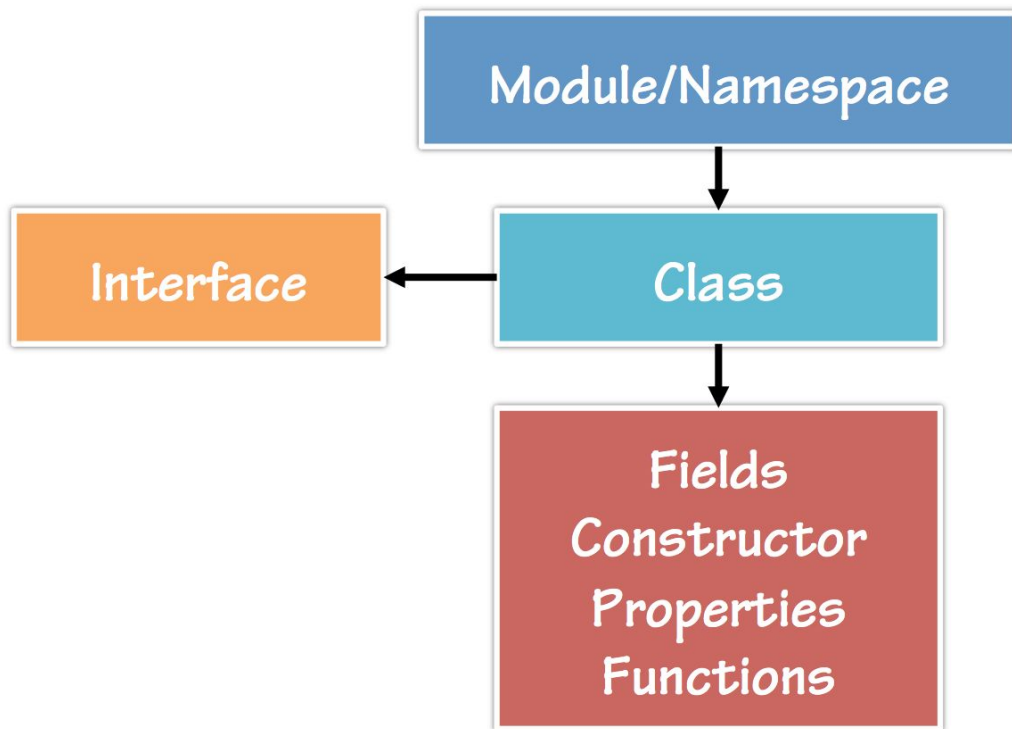

TypeScript Syntax Rules

- **TypeScript is a superset of JavaScript**
- **Follows the same syntax rules:**
 - {} brackets define code blocks
 - Semi-colons end code expressions
- **JavaScript keywords:**
 - for
 - if
 - More..

Important Keywords and Operators

| Keyword | Description |
|---------------------------|--|
| class | Container for members such as properties and functions |
| constructor | Provides initialization functionality in a class |
| exports | Export a member from a module |
| extends | Extend a class or interface |
| implements | Implement an interface |
| imports | Import a module |
| interface | Defines code contract that can be implemented by types |
| module / namespace | Container for classes and other code |
| public/private | Member visibility modifiers |
| ... | Rest parameter syntax |
| => | Arrow syntax used with definitions and functions |
| <typeName> | < > characters use to cast/convert between types |
| : | Separator between variable/parameter names and types |

Code Hierarchy

Annotations and Inferences

`var any1;`

Type could be any type (any)

`var num1: number;`

Type Annotation

`var num2: number = 2;`

Type Annotation Setting the Value

`var num3 = 3;`

Type Inference (number)

`var num4 = num3 + 100;`

Type Inference (number)

`var str1 = num1 + 'some string';`

Type Inference (string)

`var nothappy : number = num1 + 'some string';`

Error!

Dynamic and Static

TypeScript

Static typing (optional)

Type safety is a compile-time
feature

JavaScript

Dynamic typing

Type safety happens at run-time
debugging

Type Definition Files (aka Declaration Source Files)

TypeScript

```
/// <reference path="jquery.d.ts" />
```

```
declare var $;
```

```
var data = "Hello John";
```

```
$("div").text(data);
```

Helps provide
types for jquery

JavaScript

```
var data = "Hello John";
```

```
$("div").text(data);
```

Ambient Declarations do not
appear anywhere in the
JavaScript

Functions

- **Parameter types (required and optional)**
- **Arrow function expressions**
 - Compact form of function expressions
 - Omit the function keyword
 - Have scope of "this"
- **Void**
 - Used as the return type for functions that return no value

Arrow Function Expressions

TypeScript

```
var myFunc = function (h: number, w: number) {  
    return h * w;  
};
```

Omit the function
keyword

Compact return
statement

```
var myFunc = (h: number, w: number) => h * w;
```

Emit the same JavaScript

```
var myFunc = function (h, w) {  
    return h * w;  
};
```

All JavaScript is Valid TypeScript

Typings, Variables and Functions

- **Emits JavaScript**
- **Optional static typing**
 - Various types
- **Compile time checking**
- **Ambient Declarations for external references**
 - Use with typings (*.d.ts files)
- **Objects and functions**
 - Parameter types (required and optional)
 - Arrow function expressions
- **Interfaces**

The Role of Classes in TypeScript

**Classes act as containers
for different members**

TypeScript Class Members

Fields

Constructors

Properties

Functions

Defining a Class

```
class Car {  
    //Fields  
  
    //Constructor  
  
    //Properties  
  
    //Functions  
}
```

*Classes act as containers
that encapsulate code*

Defining Constructors

Constructors are used to initialize fields

```
class Car {
```

```
    engine: string;
```

Field

```
    constructor(engine: string) {
```

```
        this.engine = engine;
```

```
    }
```

```
}
```

Constructor

Shorthand way to declare a field

```
class Car {
```

```
    constructor(public engine: string) { }
```

```
}
```

Adding Functions

```
class Car {  
    engine: string;  
  
    constructor (engine: string) {  
        this.engine = engine;  
    }  
  
    start() {  
        return "Started " + this.engine;  
    }  
  
    stop() {  
        return "Stopped " + this.engine;  
    }  
}
```

Class members are
public by default

Defining Properties

```
class Car {  
    private _engine: string;  
  
    constructor(engine: string) {  
        this.engine = engine;  
    }  
  
    get engine(): string {  
        return this._engine;  
    }  
  
    set engine(value: string) {  
        if (value == undefined) throw 'Supply an Engine!';  
        this._engine = value;  
    }  
}
```

Properties act as filters and
can have get or set blocks

Instantiating a Type

*Types are instantiated
using the "new" keyword*

```
var engine = new Engine(300, 'V8');  
var car = new Car(engine);
```

Extending Types with TypeScript

Extending a Type

Types can be extended using the TypeScript "extends" keyword

```
class ChildClass extends ParentClass {  
  constructor() {  
    super();  
  }  
}
```

Child class constructor must call base class (super) constructor

Type Extension Example

```
class Auto {  
    engine: Engine;  
    constructor(engine: Engine) {  
        this.engine = engine;  
    }  
}
```

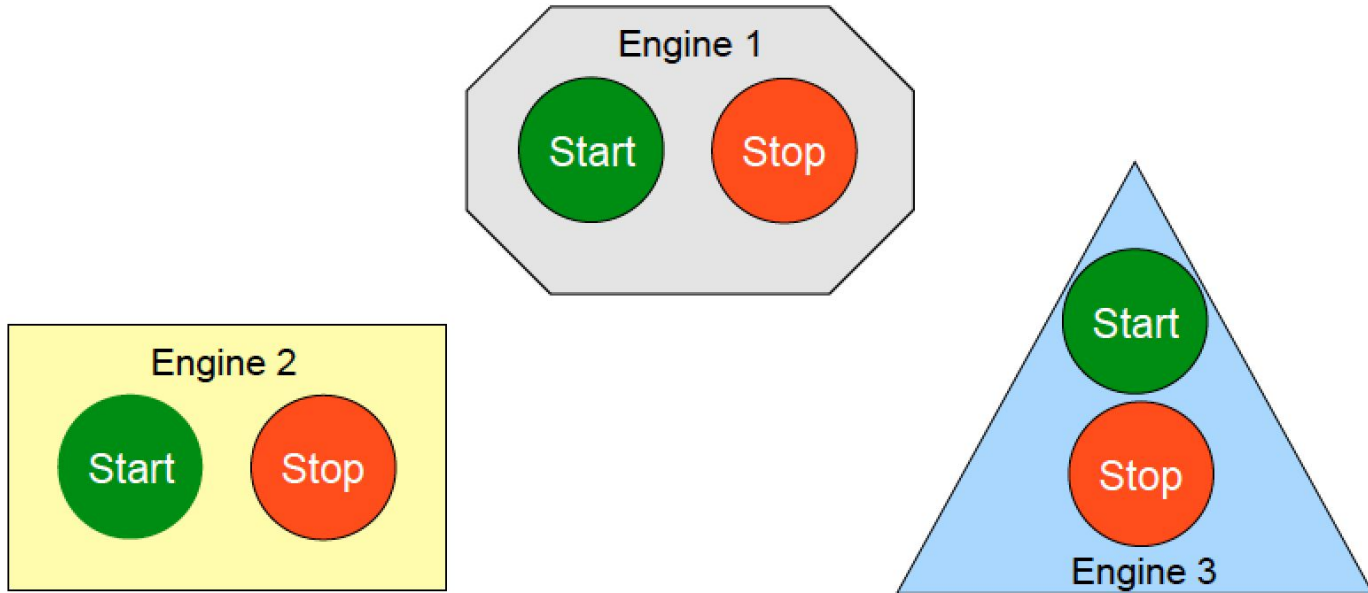

*Truck derives from
Auto*

```
class Truck extends Auto {  
    fourByFour: boolean;  
    constructor(engine: Engine, fourByFour: boolean) {  
        super(engine);  
  
        this.fourByFour = fourByFour;  
    }  
}
```

*Call base class
constructor*

What's an Interface?

- A factory requires that all engines being built have a standard "interface":

Defining an Interface

```
1 interface Action {  
2     start(message: string);  
3     stop(message: string);  
4 }  
5  
6 class Car implements Action{  
7     constructor(public engine: string) {  
8         this.engine = engine;  
9     }  
10 }  
11  
12     start(message: string) {  
13         console.log(this.engine + message);  
14     }  
15  
16     stop(message: string) {  
17         console.log(this.engine + message);  
18     }  
19 }  
20 }  
21  
22 var p = new Car('v8');  
23  
24 p.start('started');  
25
```

Interface provide a way to define a “contract” that other objects must implement

- TypeScript provides code encapsulation through classes
- Classes can inherit from other classes
- Interfaces provide a "code contract" to ensure consistency across objects
- Interfaces can extend other interfaces
